MAYO CLINIC

CENTER FOR
INDIVIDUALIZED MEDICINE

Clinical Variant Interpretation
June 9th, 2022

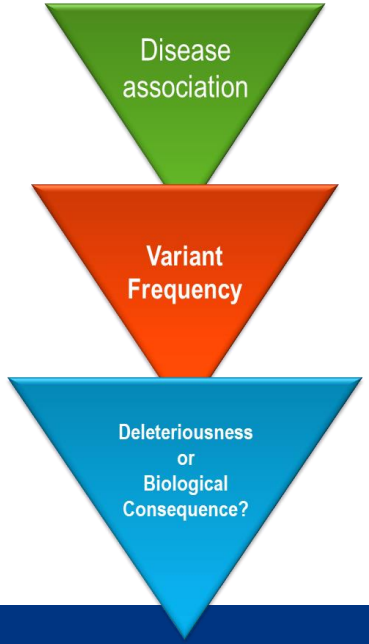
Erica Macke, PhD
Postdoctoral Research Fellow
Translational Omics Program
Quantitative Health Sciences Department
macke.erica@mayo.edu

Objectives:

- Understand basics of variant prioritization and nomenclature
- Overview of the current framework for analysis and interpretation of sequence variants for monogenic disorders
- Overview of key available resources and their utility with variant interpretation.

Variant prioritization: why does it matter?

I have detected variants in my patient sample. What information can I use to interpret them?



- Gene disease association
- Allele frequency
- In silico predictions

HGVS nomenclature

Sequence Variant Nomenclature | Recommendations | Background Materials | Recent Additions | Contact Us | Version 20.05

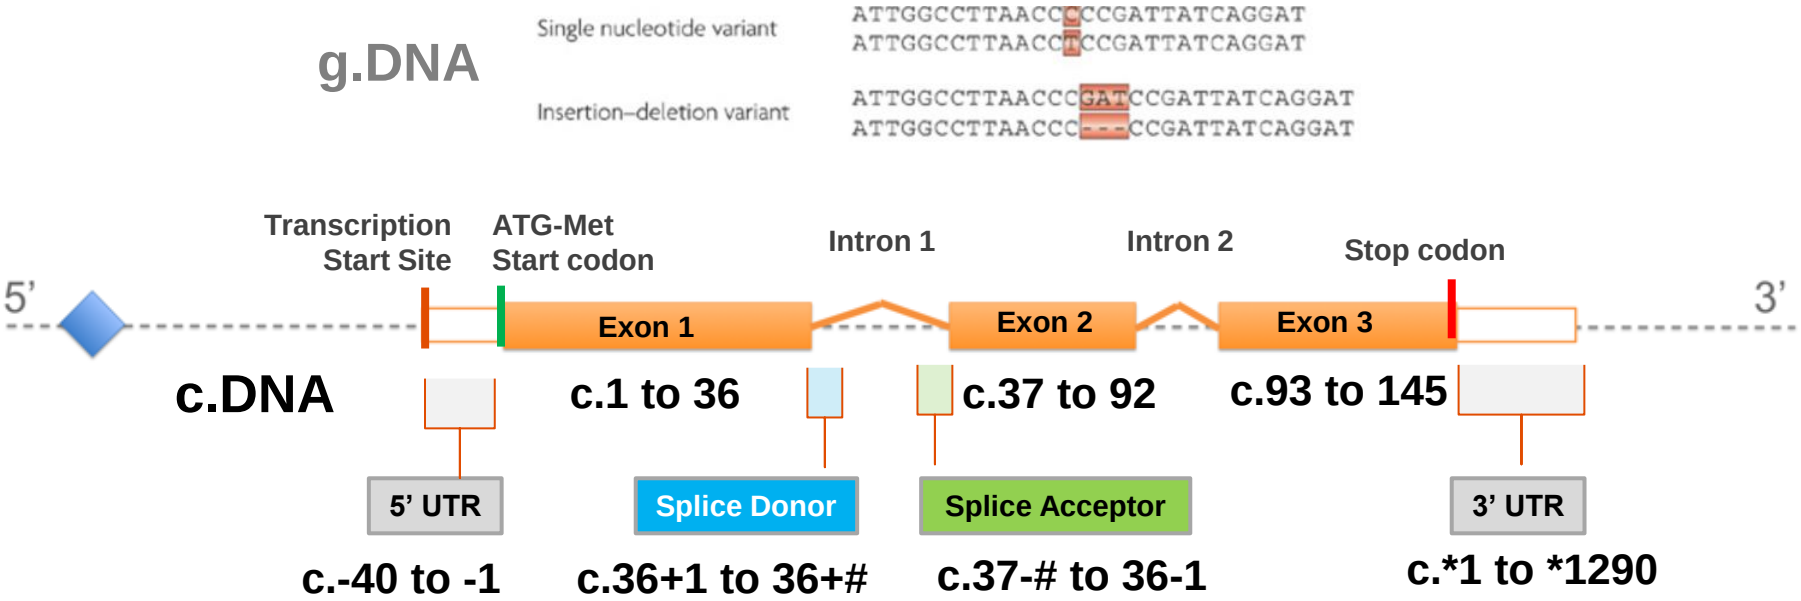
- a **letter prefix** is mandatory to indicate the type of reference sequence used. Accepted prefixes are;
  - "**c.**" for a coding DNA reference sequence
  - "**g.**" for a linear genomic reference sequence
  - "**m.**" for a mitochondrial DNA reference sequence
  - "**n.**" for a non-coding DNA reference sequence
  - "**o.**" for a circular genomic reference sequence
  - "**p.**" for a protein reference sequence
  - "**r.**" for an RNA reference sequence (transcript)
- numbering of the residues (nucleotide or amino acid) in relation to the reference sequence used should **follow the approved scheme** (*see Numbering*)

gDNA: Chr12(GRCh37): g.53703386C>G
cDNA: NM_015665.5(AAAS): c.809G>C
Protein: p.(Arg270Pro)

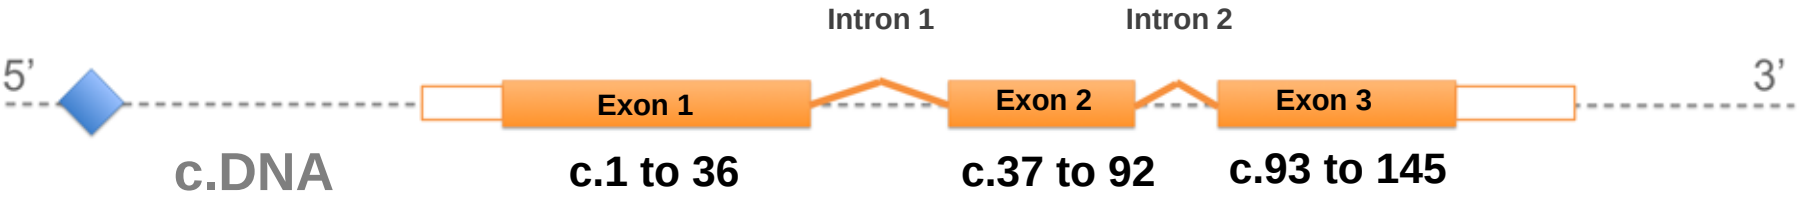
Other important considerations when looking at nomenclature

- Which reference genome is being used
- Transcript ID (one genomic variant can be described differently in the coding sequence depending on transcript)

cDNA examples



Protein level examples



Protein Consequences:

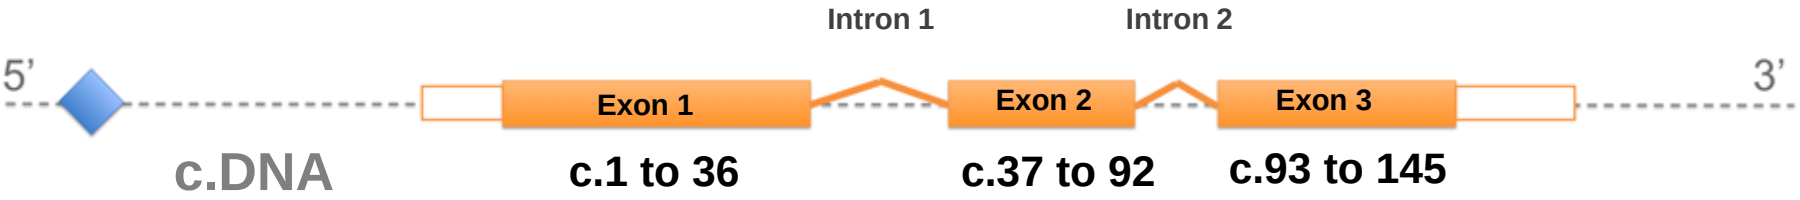
	No mutation	Point mutations			
		Silent	Nonsense	Missense	
				conservative	non-conservative
DNA level	TTC	TTT	ATC	TCC	TGC
mRNA level	AAG	AAA	UAG	AGG	ACG
protein level	Lys	Lys	STOP	Arg	Thr

MSH2
c.1590A>G
p.(Glu530=)
“synonymous”

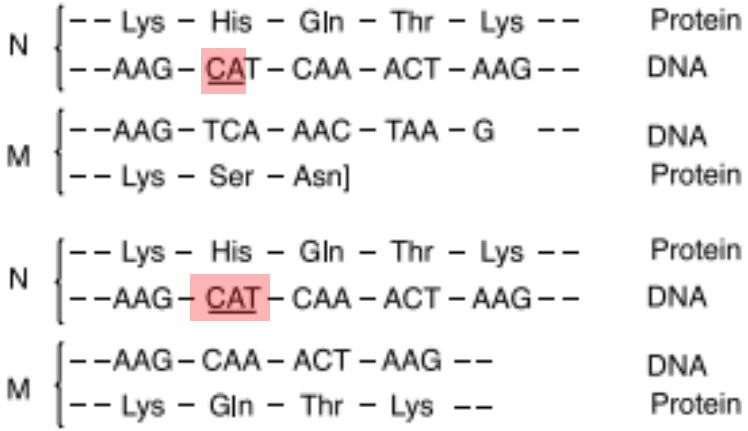
PMS2
c.730C>T
p.(Gln244*)
p.(Gln244Ter)

BRCA1
c.736T>G
p.(Leu246Val)

Protein level examples



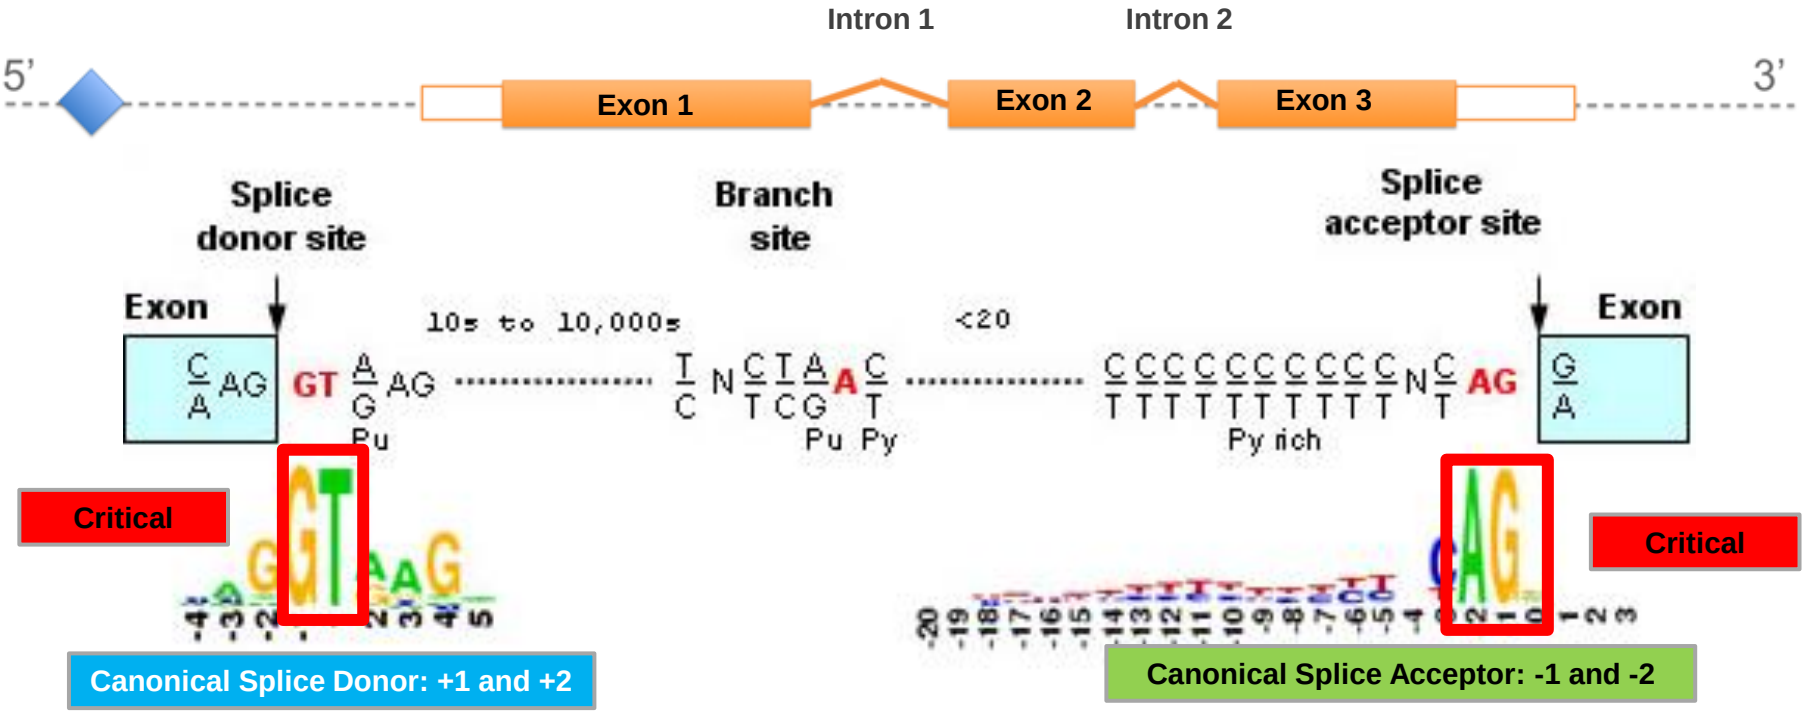
Protein Consequences



Frameshift
c.6474delCA
p.(Ser2159Asnfs*9)

In-frame deletion
c.6639_6641delTGA
p.(Asp2213del)

Splicing disruptions



VEP: Variant Effect Predictor

- VEP determines:
  - Variant effect (SNPs, insertions, deletions, CNVs or structural variants) on genes, transcripts, and protein sequence, as well as regulatory regions.
  - Location of the variants (e.g. upstream of a transcript, in coding sequence, in non-coding RNA, in regulatory regions)
  - Consequence of your variants on the protein sequence (e.g. stop gained, missense, stop lost, frameshift)
  - Known variants that match yours, and associated minor allele frequencies from the 1000 Genomes Project
  - SIFT and PolyPhen-2 scores for changes to protein sequence

Gene: BRCA1 ENSG00000012048

MAYO CLINIC

Description	BRCA1 DNA repair associated [Source:HGNC Symbol;Acc:HGNC:1100]
Gene Synonyms	BRCC1, FANCS, PPP1R53, RNF53
Location	Chromosome 17: 43,044,295-43,170,245 reverse strand.

Gene: BRCA1

Gene: BRCA1 ENSG00000012048

Description	BRCA1 DNA repair associated [Source:HGNC Symbol;Acc:HGNC:1100]
Gene Synonyms	BRCC1, FANCS, PPP1R53, RNF53
Location	Chromosome 17: 43,044,295-43,170,245 reverse strand. GRCh38:CM000679.2
About this gene	This gene has 34 transcripts (splice variants), 233 orthologues, is a member of 1 Ensembl protein family and is associated with 80 phenotypes.

Gene: BRCA1
Gene: BRCA1 ENSG00000012048
Description
BRCA1 DNA repair associated [Source:HGNC Symbol;Acc:HGNC:1100]
Gene Synonyms
BRCC1, FANCS, PPP1R53, RNF53
Location
Chromosome 17: 43,044,295-43,170,245 reverse strand.

Which transcript should I use?
For automated analysis, if you are doing NGS analysis and you need to capture all possible transcripts, GENCODE provides one of the most comprehensive gene sets.
For human genetics or variant annotation, a more restricted transcript set is usually sufficient and "NCBI RefSeq" is the standard with the newest MANE catalogue providing the clinically relevant transcripts.

Variant Interpretation: Rationale

- Is a previously published variant associated with a disease phenotype pathogenic?
- Are all variants observed in a control population benign?
- What evidence to we use to ultimately classify a variant?
- How do we ensure consistency among clinicians, clinical laboratories, and researchers?

15-20 years ago…

- If you thought a gene may be implicated in a specific disease:
  - You could screen a cohort of patients and look for variants in said gene
  - If you identified a variant in a patient and did not find it in 50 control samples (100 alleles!!!) you could deem this as a pathogenic variant
- Does this make sense statistically?

Common framework and criteria for germline variant classification

Likely Benign
Benign

2015 ACMG guidelines

Standards and guidelines for the interpretation of sequence variants: a joint consensus recommendation of the American College of Medical Genetics and Genomics and the Association for Molecular Pathology

Sue Richards, PhD[1], Nazneen Aziz, PhD[2,16], Sherri Bale, PhD[3], David Bick, MD[4], Soma Das, PhD[5], Julie Gastier-Foster, PhD[6,7,8], Wayne W. Grody, MD, PhD[9,10,11], Madhuri Hegde, PhD[12], Elaine Lyon, PhD[13], Elaine Spector, PhD[14], Karl Voelkerding, MD[13] and Heidi L. Rehm, PhD[15]; on behalf of the ACMG Laboratory Quality Assurance Committee

- These recommendations primarily apply to genetic tests used in clinical laboratories including **genotyping, single genes, panels, exomes and genomes.**
- **It is not intended** for the interpretation of **somatic variation, pharmacogenomic variants, or variants in genes associated with multigenic non-Mendelian complex disorders.**
- Care must be taken when applying these rules to candidate genes ("genes of uncertain significance", **GUS**)
- This report recommends the use of specific standard terminology: 'pathogenic', 'likely pathogenic', 'uncertain significance', 'likely benign', and 'benign' to describe variants identified in **Mendelian disorders.**

Class
Pathogenic
Likely Pathogenic
Variant of Uncertain Significance
Likely Benign
Benign

We interpret by sorting variants into categories

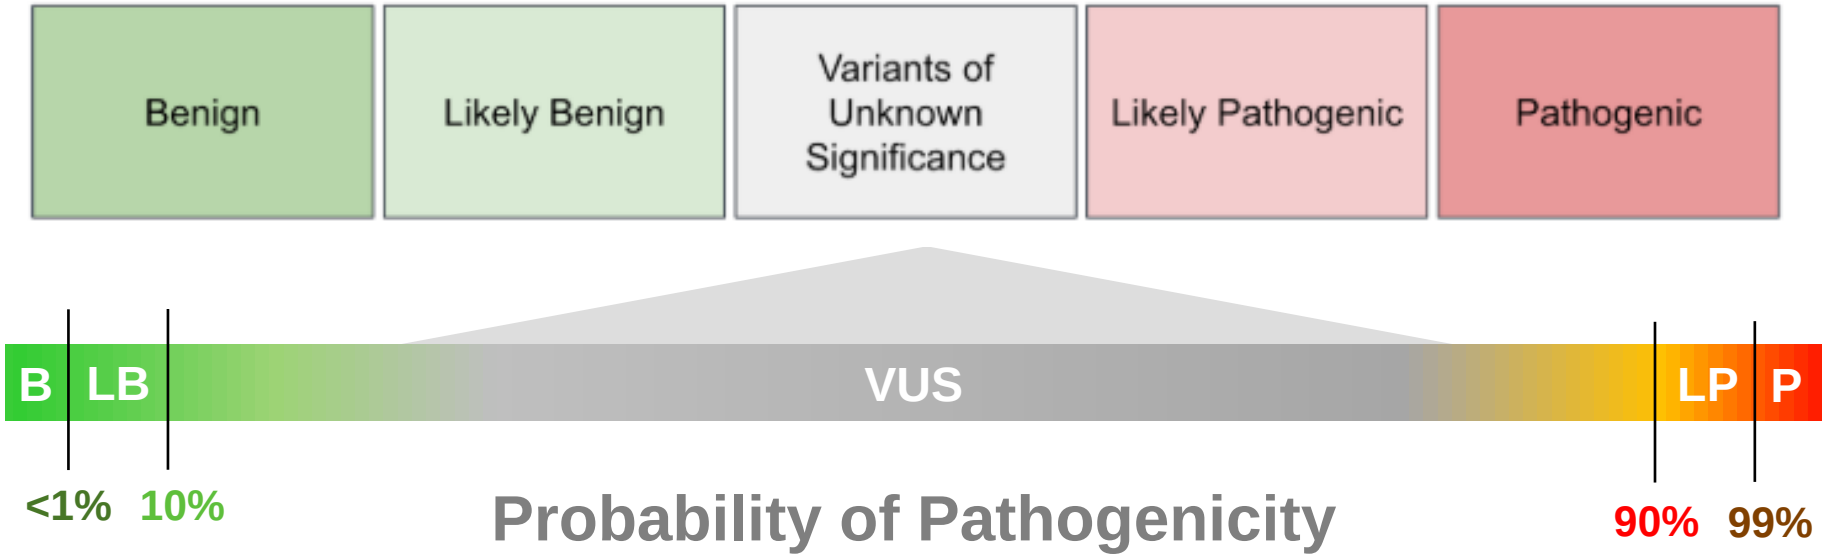
***Variant:** An alteration in the normal sequence of a gene:

Benign	Variants of Unknown Significance	Pathogenic
A variant that does not appear to have a *deleterious* effect often associated with a "normal" or no human phenotype.	A variant whose association with disease risk is unknown.	A variant which is proven to be deleterious to protein or gene function and is associated with a particular human phenotype or disease

Caution: **A deleterious variant is not always pathogenic or disease causing.**

What is `Likely`?

The rules proposed to classify sequence variants follows is a heuristic system for variant classification that is compatible with a formal, quantitative, Bayesian classifier.



2015 ACMG Guidelines

Standards and guidelines for the interpretation of sequence variants: a joint consensus recommendation of the American College of Medical Genetics and Genomics and the Association for Molecular Pathology

Sue Richards, PhD[1], Nazneen Aziz, PhD[2,16], Sherri Bale, PhD[3], David Bick, MD[4], Soma Das, PhD[5], Julie Gastier-Foster, PhD[6,7,8], Wayne W. Grody, MD, PhD[9,10,11], Madhuri Hegde, PhD[12], Elaine Lyon, PhD[13], Elaine Spector, PhD[14], Karl Voelkerding, MD[13] and Heidi L. Rehm, PhD[15]; on behalf of the ACMG Laboratory Quality Assurance Committee

- The guideline defined 28 criteria, with codes that addressed types of variant evidence. Each evidence type or criterion code was assigned a direction, benign (B) or pathogenic (P), and a level of strength: stand-alone (A), very strong (VS), strong (S), moderate (M), or supporting (P).

	Benign		Pathogenic			
	Strong	Supporting	Supporting	Moderate	Strong	Very strong
Population data	MAF is too high for disorder BA1/BS1 **OR** observation in controls inconsistent with disease penetrance BS2			Absent in population databases PM2	Prevalence in affecteds statistically increased over controls PS4	
Computational and predictive data		Multiple lines of computational evidence suggest no impact on gene /gene product BP4 Missense in gene where only truncating cause disease BP1 Silent variant with non predicted splice impact BP7 In-frame indels in repeat w/out known function BP3	Multiple lines of computational evidence support a deleterious effect on the gene /gene product PP3	Novel missense change at an amino acid residue where a different pathogenic missense change has been seen before PM5 Protein length changing variant PM4	Same amino acid change as an established pathogenic variant PS1	Predicted null variant in a gene where LOF is a known mechanism of disease PVS1
Functional data	Well-established functional studies show no deleterious effect BS3		Missense in gene with low rate of benign missense variants and path. missenses common PP2	Mutational hot spot or well-studied functional domain without benign variation PM1	Well-established functional studies show a deleterious effect PS3	
Segregation data	Nonsegregation with disease BS4		Cosegregation with disease in multiple affected family members PP1	Increased segregation data →		
De novo data				De novo (without paternity & maternity confirmed) PM6	De novo (paternity and maternity confirmed) PS2	
Allelic data		Observed in *trans* with a dominant variant BP2 Observed in *cis* with a pathogenic variant BP2		For recessive disorders, detected in trans with a pathogenic variant PM3		
Other database		Reputable source w/out shared data = benign BP6	Reputable source = pathogenic PP5			
Other data		Found in case with an alternate cause BP5	Patient's phenotype or FH highly specific for gene PP4			

ACMG 2015 guidelines discrete criteria have a strong quantitative correlation with the odds of pathogenicity of a variant.

		BENIGN CRITERIA		PATHOGENIC CRITERIA			
Strength of Evidence		Strong	Supporting	Supporting	Moderate	Strong	Very Strong
Odds of Pathogenicity*		-18.7	-2.08	2.08	4.33	18.7	350.0
Evidence Category and Corresponding ACMG/AMP Codes	Population Data	*BA1*+ BS1 BS2			PM2	PS4	
	Allelic Evidence & Co-Segregation Data	BS4	BP2 BP5	PP1 →	PM3 PM6	PS2	
	Computation & Predictive Data		BP1 BP3 BP4 BP7	PP2 PP3	PM1 PM4 PM5	PS1	PVS1
	Functional Data	BS3				PS3	
	Other		BP6	PP4 PP5			

Table 5 Rules for combining criteria to classify sequence variants

Pathogenic	(i) 1 Very strong (PVS1) *AND*

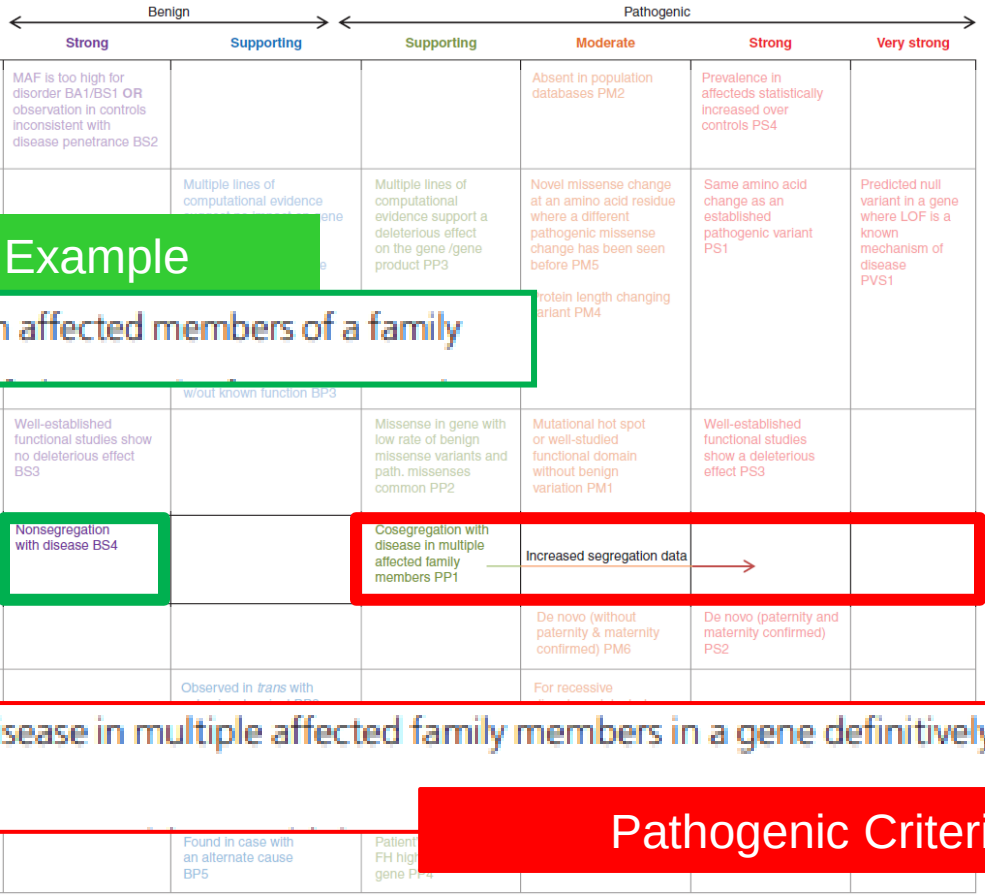
Conflicting evidence example:

PS4 + PM2 + BP2 + BP4

= Variant of Uncertain Significance (VUS or VOUS)



Benign Criteria Example

BS4 Lack of segregation in affected members of a family

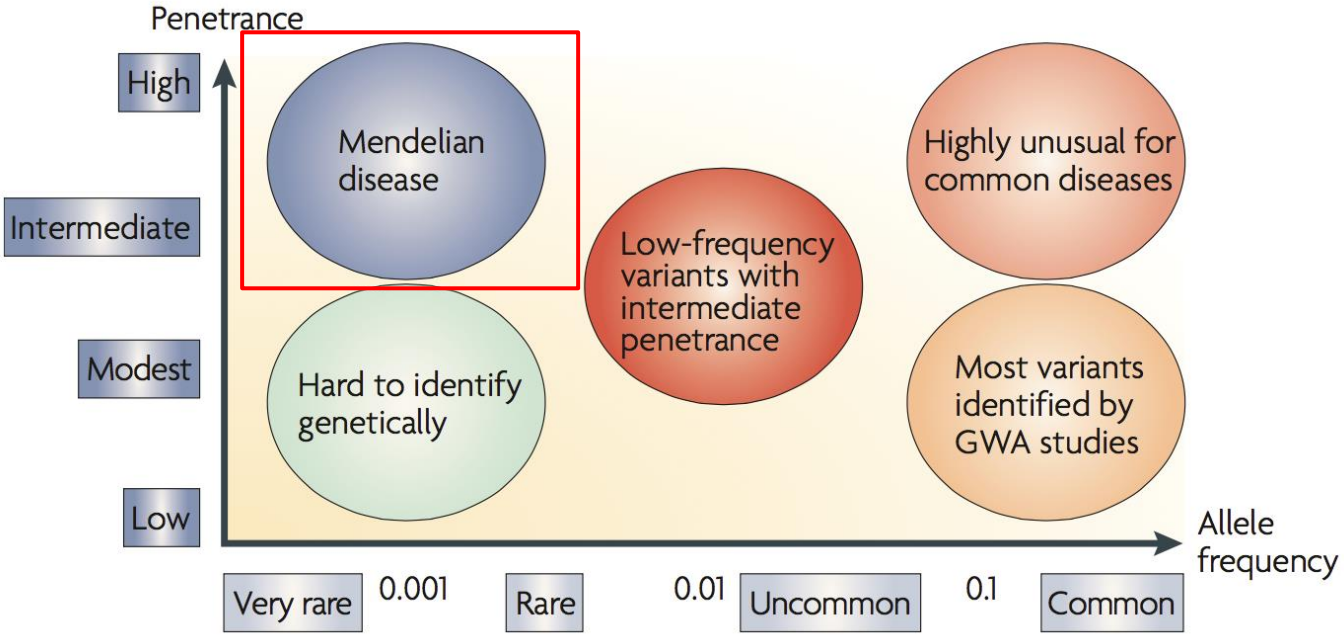
Segregation Data Criterion

PP1 Cosegregation with disease in multiple affected family members in a gene definitively known to cause the disease

Pathogenic Criteria Example

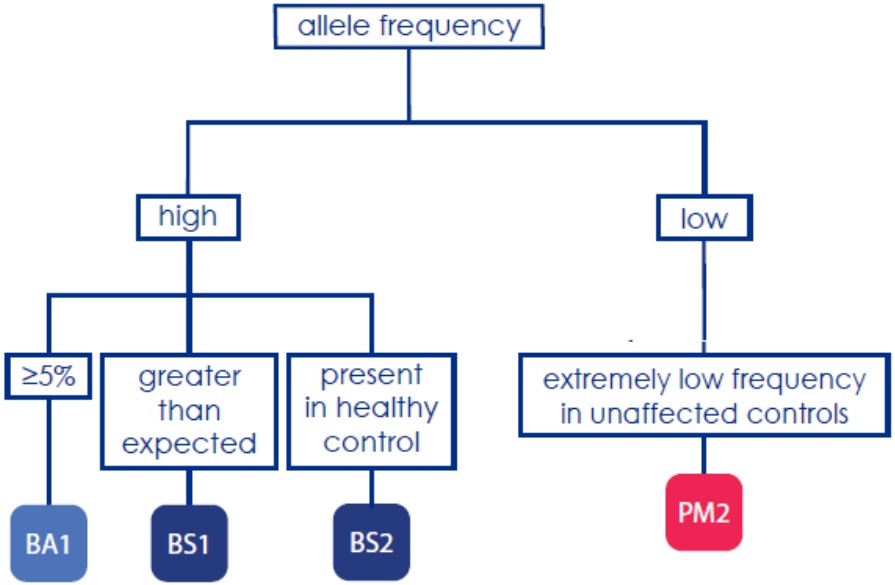
	Benign		Pathogenic			
	Strong	Supporting	Supporting	Moderate	Strong	Very strong
Population data	MAF is too high for disorder BA1/BS1 **OR** observation in controls inconsistent with disease penetrance BS2			Absent in population databases PM2	Prevalence in affecteds statistically increased over controls PS4	
Computational and predictive data		Multiple lines of computational evidence suggest no impact on gene /gene product BP4 Missense in gene where only truncating cause disease BP1 Silent variant with non predicted splice impact BP7 In-frame indels in repeat w/out known function BP3	Multiple lines of computational evidence support a deleterious effect on the gene /gene product PP3	Novel missense change at an amino acid residue where a different pathogenic missense change has been seen before PM5 Protein length changing variant PM4	Same amino acid change as an established pathogenic variant PS1	Predicted null variant in a gene where LOF is a known mechanism of disease PVS1
Functional data	Well-established functional studies show no deleterious effect BS3		Missense in gene with low rate of benign missense variants and path. missenses common PP2	Mutational hot spot or well-studied functional domain without benign variation PM1	Well-established functional studies show a deleterious effect PS3	
Segregation data	Nonsegregation with disease BS4		Cosegregation with disease in multiple affected family members PP1	Increased segregation data →		
De novo data				De novo (without paternity & maternity confirmed) PM6	De novo (paternity and maternity confirmed) PS2	
Allelic data		Observed in *trans* with a dominant variant BP2 Observed in *cis* with a pathogenic variant BP2		For recessive disorders, detected in trans with a pathogenic variant PM3		
Other database		Reputable source w/out shared data = benign BP6	Reputable source = pathogenic PP5			
Other data		Found in case with an alternate cause BP5	Patient's phenotype or FH highly specific for gene PP4			

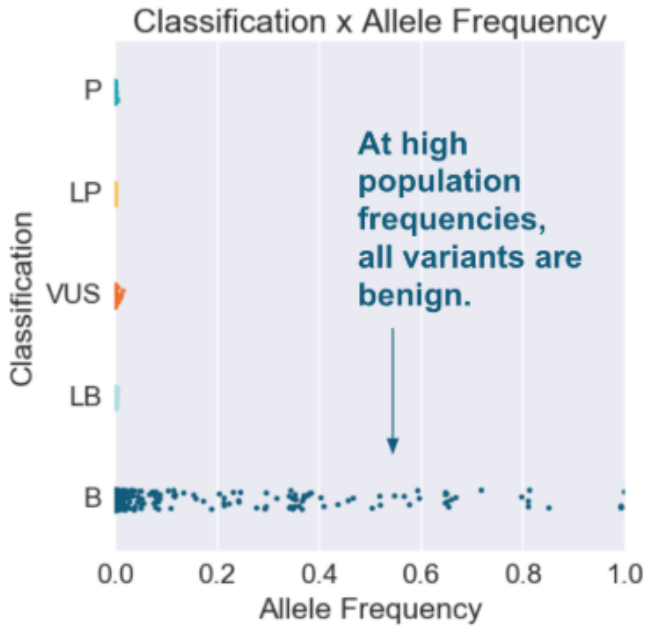
Allele Frequency (BA1, BS1, PM2)
How common is this variant?



https://gnomad.broadinstitute.org/

	Benign		Pathogenic			
	Strong	Supporting	Supporting	Moderate	Strong	Very strong
Population data	MAF is too high for disorder BA1/BS1 **OR** observation in controls inconsistent with disease penetrance BS2			Absent in population databases PM2	Prevalence in affecteds statistically increased over controls PS4	





The cutoffs of each of these criteria depends on many factors such as: Prevalence of disease, age of onset, and penetrance

Allele Frequency (BA1, BS1, PM2)
How common is this variant?

BA1:

>5% allele frequency in any general continental population of at least 2,000 alleles for a gene without a gene or variant specific recommendation.

BS1:

Allele frequency is greater than expected for disorder (lower than BA1)

PM2:

Absent from controls (or at an extremely low frequency if recessive).

*ACMG/AMP criteria selected does not match the classification as these variants are common low-penetrant variants and the ACMG/AMP guidelines are not designed for this variant type

Detected at >5% MAF only in Finnish population (see text).

Genomic coordinates on build GRCh37

AFR: African/African American, EAS: East Asian, NFE: Non-Finnish European, AMR: Latino, FIN=Finnish

Allele Frequency (BA1, BS1, PM2)
Other considerations…

What is a control population? Unselected?

For dominant disorders (AD):
Adult-onset disorders could be represented in the gnomAD database in still unaffected probands. Instead of controls the database could be refer to better as "general population".

PM2:
Absent from controls (or at an extremely low frequency if recessive).

ClinGen Sequence Variant Interpretation Recommendation for PM2 - Version 1.0
Working Group Page: https://clinicalgenome.org/working-groups/sequence-variant-interpretation/
Date Approved: September 4, 2020

SVI Recommendation for Absence/Rarity (PM2) - Version 1.0

The ClinGen Sequence Variant Interpretation (SVI) Working Group proposes decreasing the weight of criterion PM2 ("Absent from controls, or at extremely low frequency if recessive, in Exome Sequencing Project, 1000Genomes Project, or Exome Aggregation Consortium") from a Moderate strength level to a Supporting strength level (PM2_Supporting).

PM2_supporting

Demotion of this category to supporting is currently recommended.

https://clinicalgenome.org/site/assets/files/5182/pm2_-_svi_recommendation_-_approved_sept2020.pdf

	Benign		Pathogenic			
	Strong	**Supporting**	**Supporting**	**Moderate**	**Strong**	**Very strong**
Population data	MAF is too high for disorder BA1/BS1 **OR** observation in controls inconsistent with disease penetrance BS2			Absent in population databases PM2	Prevalence in affecteds statistically increased over controls PS4	
Computational and predictive data		Multiple lines of computational evidence suggest no impact on gene /gene product BP4 Missense in gene where only truncating cause disease BP1 Silent variant with non predicted splice impact BP7 In-frame indels in repeat w/out known function BP3	Multiple lines of computational evidence support a deleterious effect on the gene /gene product PP3	Novel missense change at an amino acid residue where a different pathogenic missense change has been seen before PM5 Protein length changing variant PM4	Same amino acid change as an established pathogenic variant PS1	Predicted null variant in a gene where LOF is a known mechanism of disease PVS1
Functional data	Well-established functional studies show no deleterious effect BS3		Missense in gene with low rate of benign missense variants and path. missenses common PP2	Mutational hot spot or well-studied functional domain without benign variation PM1	Well-established functional studies show a deleterious effect PS3	
Segregation data	Nonsegregation with disease BS4		Cosegregation with disease in multiple affected family members PP1	Increased segregation data →		
De novo data				De novo (without paternity & maternity confirmed) PM6	De novo (paternity and maternity confirmed) PS2

- Focus on the "Pathogenic criteria"

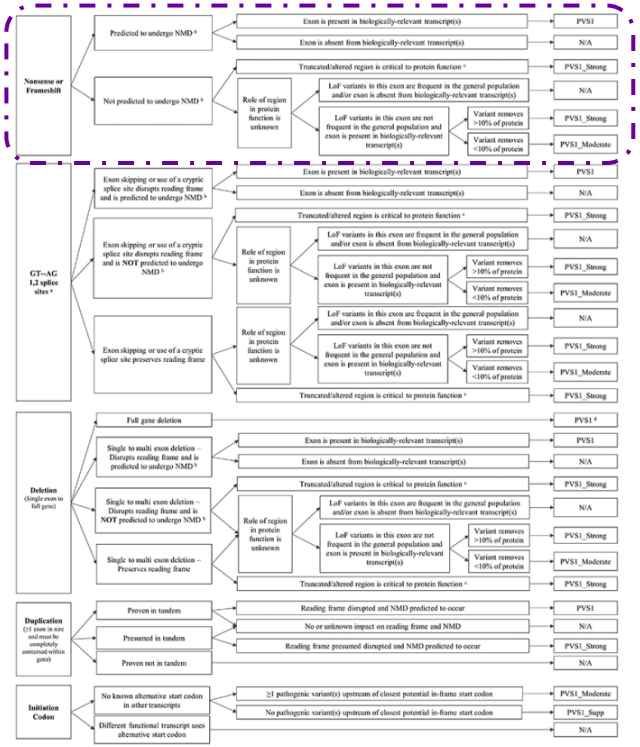
Richards CS et al. *Gen Med.* 2015;17:405-423

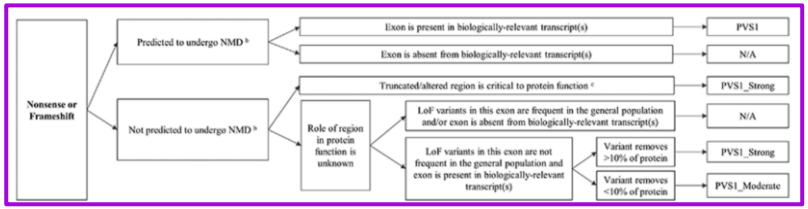
Computational and predictive data		Multiple lines of computational evidence suggest no impact on gene /gene product BP4 Missense in gene where only truncating cause disease BP1 Silent variant with non predicted splice impact BP7 In-frame indels in repeat w/out known function BP3	Multiple lines of computational evidence support a deleterious effect on the gene /gene product PP3	Novel missense change at an amino acid residue where a different pathogenic missense change has been seen before PM5 Protein length changing variant PM4	Same amino acid change as an established pathogenic variant PS1	Predicted null variant in a gene where LOF is a known mechanism of disease PVS1

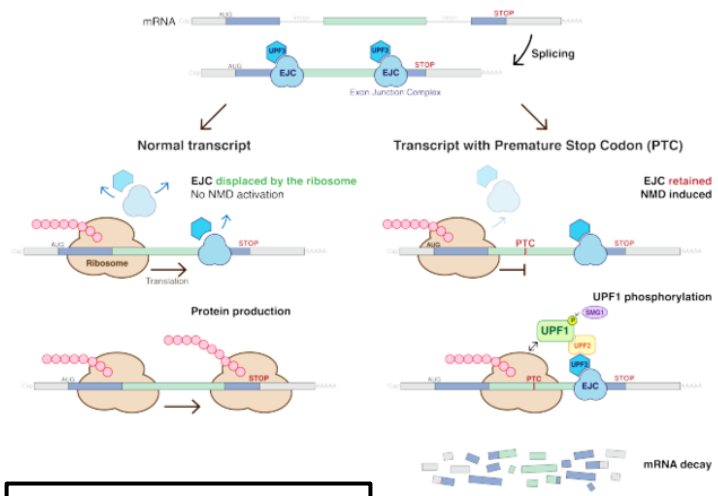
Loss of Function Criteria (PVS1) (only "very strong" level of evidence)

- Null variant in a gene where loss of function (LoF) is a known mechanism of disease.

PVS1



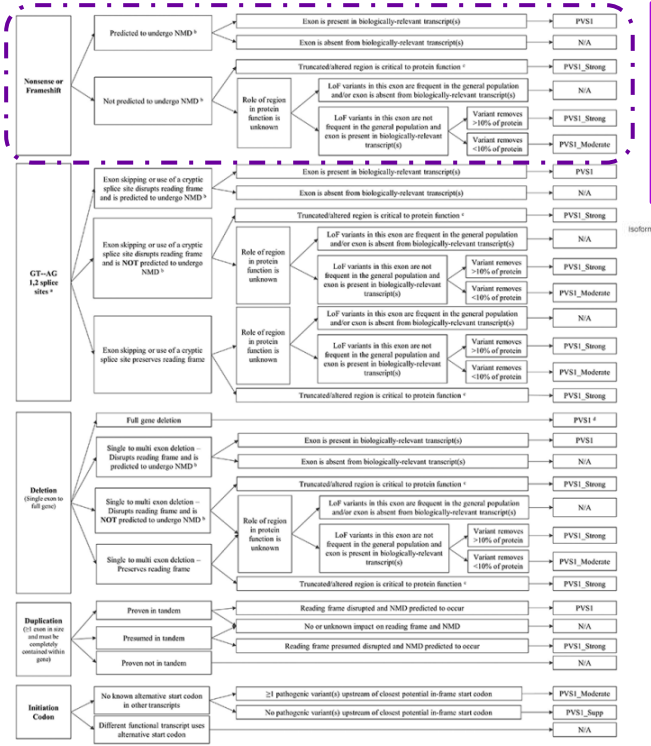


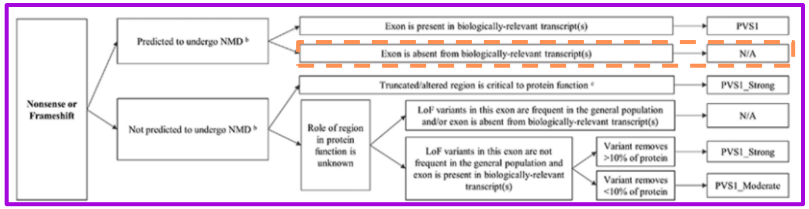


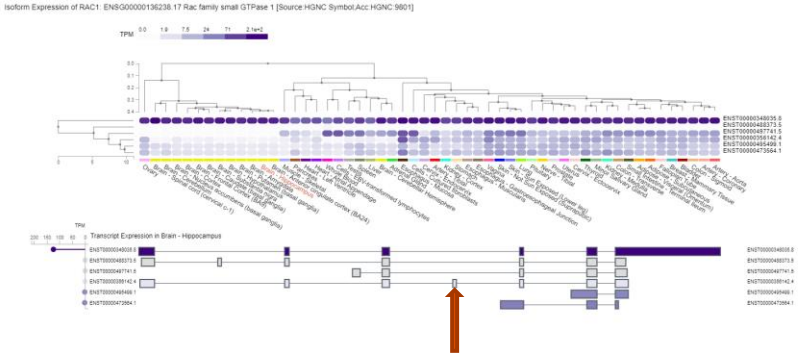
If the termination codon is downstream of or within about 50 nucleotides of the final exon-junction complex then the transcript is translated normally.

https://onlinelibrary.wiley.com/doi/full/10.1002/humu.236

PVS1







What if I had a variant here?

How do I know if loss of function variants cause disease?

- pLI score - Probability a gene is haploinsufficient - where heterozygous LoFs are not tolerated. >0.9 is a common threshold. Particularly good for autosomal dominant disease.

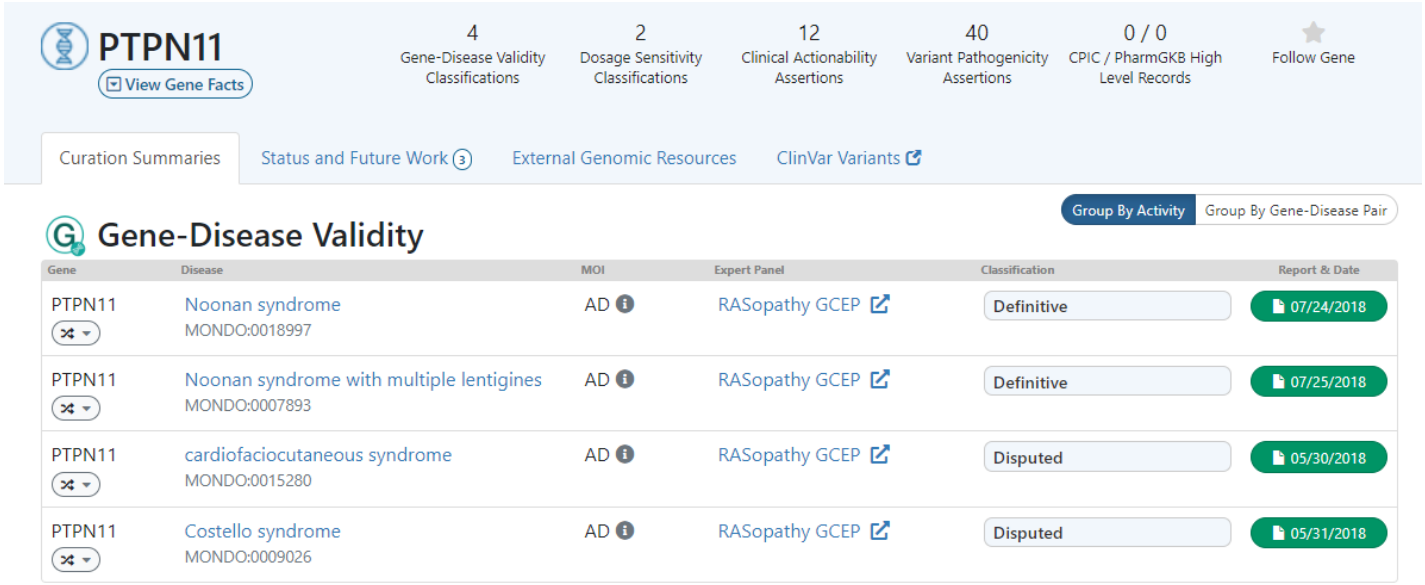
- Most of the variants associated with the phenotype are Missense

ClinGen



- Noonan syndrome is believed to be caused **by gain-of-function** defects in *PTPN11* (PMID:11992261), and LEOPARD syndrome is believed to be caused by **dominant-negative mechanisms** (PMID: 16358218). Evidence gathered for the haploinsufficiency rating for this gene is related to the metachondromatosis phenotype.

Computational and predictive data		Multiple lines of computational evidence suggest no impact on gene /gene product BP4 Missense in gene where only truncating cause disease BP1 Silent variant with non predicted splice impact BP7 In-frame indels in repeat w/out known function BP3	Multiple lines of computational evidence support a deleterious effect on the gene /gene product PP3	Novel missense change at an amino acid residue where a different pathogenic missense change has been seen before PM5 Protein length changing variant PM4	Same amino acid change as an established pathogenic variant PS1	Predicted null variant in a gene where LOF is a known mechanism of disease PVS1

PS1

PS1	Same amino acid change as a previously established pathogenic variant regardless of nucleotide change Example: Val->Leu caused by either G>C or G>T in the same codon

Leu257Pro - Pathogenic

CUU → CCU

Leu257His - ???

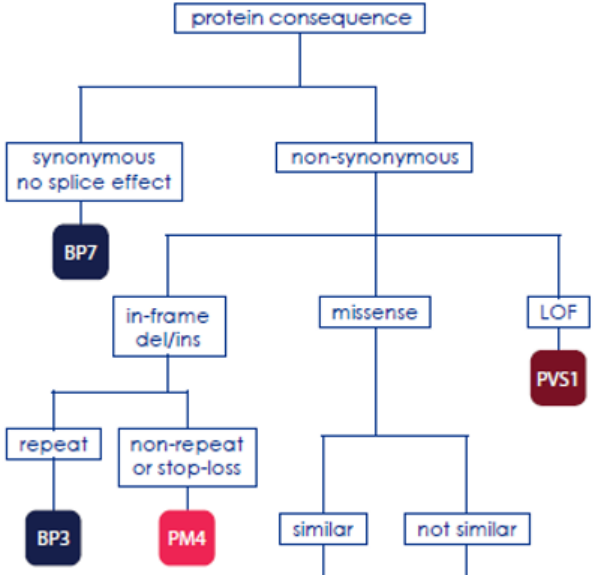
CUU → CAU

Caveat: Beware of changes that impact splicing rather than at the amino acid/protein level

Computational and predictive data		Multiple lines of computational evidence suggest no impact on gene /gene product BP4 Missense in gene where only truncating cause disease BP1 Silent variant with non predicted splice impact BP7 In-frame indels in repeat w/out known function BP3	Multiple lines of computational evidence support a deleterious effect on the gene /gene product PP3	Novel missense change at an amino acid residue where a different pathogenic missense change has been seen before PM5 Protein length changing variant PM4	Same amino acid change as an established pathogenic variant PS1	Predicted null variant in a gene where LOF is a known mechanism of disease PVS1

PM4

- Protein length changes due to in-frame deletions/insertions in a non-repeat region or stop-loss variants.



In-frame removal or insertion of amino acids

PM4

Protein length changes as a result of in-frame deletions/insertions

NM_000179.3(MSH6):
c.535_546del
p.(Ala179_Ala182del)

- Insertions/deletions that occur in repetitive regions are more likely to be of little functional impact; therefore, it is important to assess the surrounding sequence for repetitiveness using a genome browser.
- It can also help to assess population databases, such gnomAD, for high confidence variant calls that indicate the site is multi-allelic, which could indicate that the region is prone to indels that are generally tolerated, depending on the overall allele frequency.
- It is important to verify the functional impact the deletion or insertion might have. Does it affect the zinc-fingers of a transcription factor? Does it remove important aminoacids in the catalytic site?
- To prevent double-counting of this evidence type, we recommend that PM4 should not be applied for any variant in which PVS1, at any strength level, is also applied.

Stop loss: Protein extending variants

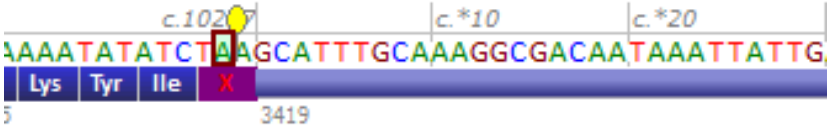
PM4

Protein length changes as a result of in-frame deletions/insertions

PM4

Stop-loss variant

- When a variant results in loss of the termination codon (stop-loss variant), the protein is extended; if a variant creates a premature termination codon (nonsense variant), the protein is shortened.



NM_000059.3(BRCA2):
c.10256_10257insT
p.(*3419Tyrext*18)

Computational and predictive data		Multiple lines of computational evidence suggest no impact on gene /gene product BP4 Missense in gene where only truncating cause disease BP1 Silent variant with non predicted splice impact BP7 In-frame indels in repeat w/out known function BP3	Multiple lines of computational evidence support a deleterious effect on the gene /gene product PP3	Novel missense change at an amino acid residue where a different pathogenic missense change has been seen before PM5 Protein length changing variant PM4	Same amino acid change as an established pathogenic variant PS1	Predicted null variant in a gene where LOF is a known mechanism of disease PVS1

- PP3

PP3	Multiple lines of computational evidence support a deleterious effect on the gene or gene product (conservation, evolutionary, splicing impact, etc)

Computational Impact Prediction

Computational Impact Prediction

Considerations

PP3

BP4

- PP3 or BP4 can be used only once in a variant. Many algorithms used the same or very similar training data for their predictions, each algorithm cannot be counted as an independent criterion.
- Consistent threshold for the tool(s) should be used for all the variants in that gene.
- Currently, a **meta-predictor such as REVEL** may be used in place of multiple predictors in the in silico analysis of missense variants.
- Splicing in silico tools can be difficult to utilize and the interpretation is often not standardized.

Computational Impact Prediction

Splicing Scores

PP3

BP4

BP7

A synonymous (silent) variant for which splicing prediction algorithms predict no impact to the splice consensus sequence nor the creation of a new splice site AND the nucleotide is not highly conserved.

Richards CS et al. *Gen Med.* 2015;17:405-423

Computational Impact Prediction

A Commonly Used Powerful Splicing Tool

PP3

BP4

BP7

SpliceAI

Deep neural network based on pre-mRNA transcript sequences that predicts splice sites using long-range primary genomic sequence flanking each position as input
(+/-50 bp as default; +/-10,000 bp maximum).

https://spliceailookup.broadinstitute.org/

Δ type	Δ score	pre-mRNA position
Acceptor Loss	0.00	
Donor Loss	0.72	0 bp
Acceptor Gain	0.00	
Donor Gain	0.01	-47 bp

SpliceAI provides a table with delta scores (0-1) for acceptor loss, donor loss, acceptor gain, and donor gain within the designated flanking sequence. The delta score indicates the probability that the variant will alter splicing at the pre-mRNA position indicated

Scores are not deterministic of biological effect/deleteriousness, they are used as “supporting evidence”

gDNA: Chr6(GRCh37):g.51720765A>G
cDNA: NM_138694.3(PKHD1):c.7837T>C
Protein: p.Trp2613Arg

Polyphen-2: Probably damaging
CADD: 29
M-CAP: Probably
PredictSNP2: Deleterious

Scores agree towards SNV being deleterious

Likelihood of pathogenicity is affected, not determined.

	Benign		Pathogenic			
	Strong	**Supporting**	**Supporting**	**Moderate**	**Strong**	**Very strong**
Population data	MAF is too high for disorder BA1/BS1 **OR** observation in controls inconsistent with disease penetrance BS2			Absent in population databases PM2	Prevalence in affecteds statistically increased over controls PS4	
Computational and predictive data		Multiple lines of computational evidence suggest no impact on gene /gene product BP4 Missense in gene where only truncating cause disease BP1 Silent variant with non predicted splice impact BP7 In-frame indels in repeat w/out known function BP3	Multiple lines of computational evidence support a deleterious effect on the gene /gene product PP3	Novel missense change at an amino acid residue where a different pathogenic missense change has been seen before PM5 Protein length changing variant PM4	Same amino acid change as an established pathogenic variant PS1	Predicted null variant in a gene where LOF is a known mechanism of disease PVS1
Functional data	Well-established functional studies show no deleterious effect BS3		Missense in gene with low rate of benign missense variants and path. missenses common PP2	Mutational hot spot or well-studied functional domain without benign variation PM1	Well-established functional studies show a deleterious effect PS3	
Segregation data	with disease BS4		disease in multiple affected family members PP1	Increased segregation data →

Other data		Found in case with an alternate cause BP5	Patient's phenotype or FH highly specific for gene PP4			

Functional Evidence:

PS3

Functional Consequence

Criteria for classifying pathogenic variants

Well-established *in vitro* or *in vivo* functional studies supportive of a damaging effect on the gene or gene product.

Note:

Functional studies that have been validated and shown to be reproducible and robust in a clinical diagnostic laboratory setting are considered the most well established.

BS3

No Functional Consequence

Criteria for classifying benign variants

Well-established *in vitro* or *in vivo* functional studies show no damaging effect on protein function or splicing.

What defines a "well established" functional study or assay? How reliable? This is not simple.

Functional Evidence:

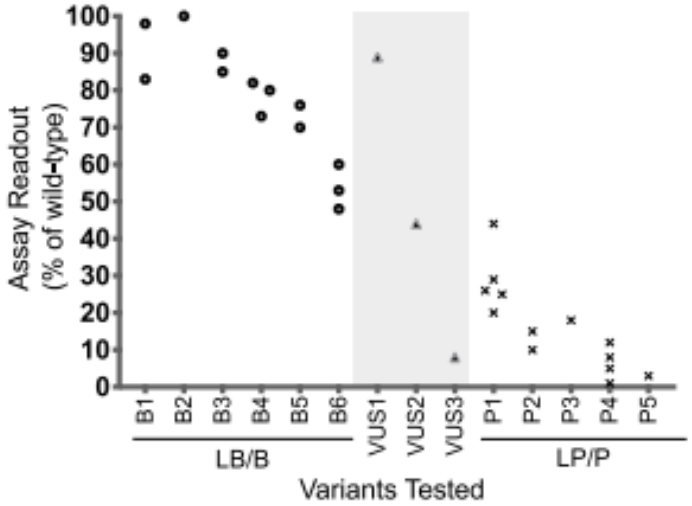
GUIDELINE Open Access

Recommendations for application of the functional evidence PS3/BS3 criterion using the ACMG/AMP sequence variant interpretation framework

Sarah E. Brnich[1], Ahmad N. Abou Tayoun[2], Fergus J. Couch[3], Garry R. Cutting[4], Marc S. Greenblatt[5], Christopher D. Heinen[6], Dona M. Kanavy[1], Xi Luo[7], Shannon M. McNulty[1], Lea M. Starita[8,9], Sean V. Tavtigian[10], Matt W. Wright[11], Steven M. Harrison[12], Leslie G. Biesecker[13], Jonathan S. Berg[1*] and On behalf of the Clinical Genome Resource Sequence Variant Interpretation Working Group

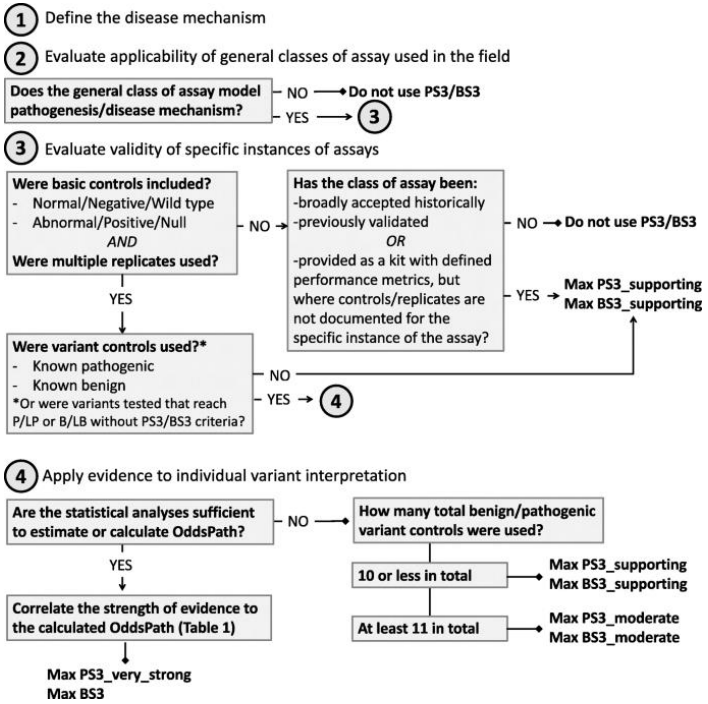
Table 3 Evidence strength equivalent of odds of pathogenicity

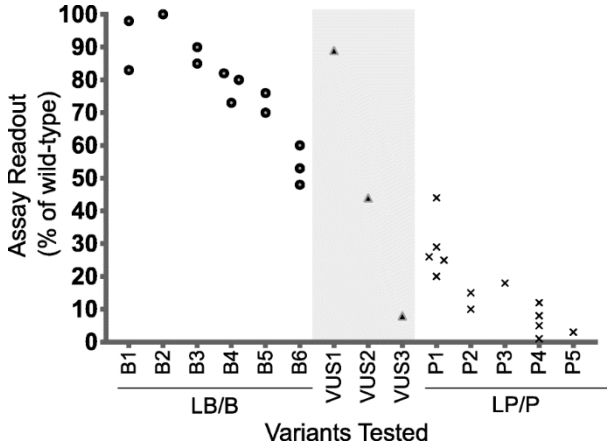
Odds of pathogenicity (OddsPath)	Evidence strength equivalent
< 0.053	BS3
< 0.23	BS3_moderate*
< 0.48	BS3_supporting
0.48–2.1	Indeterminate
> 2.1	PS3_supporting
> 4.3	PS3_moderate
> 18.7	PS3
> 350	PS3_very_strong



- Most functional evidence under these recommendations is demoted to PS3_supporting and in order to increase to moderate or strong, need to consider appropriate level of controls.
- Always consider if a test or assay is measuring the protein function or one of many.

Decision Tree to guide PS3/BS3 criterion





“Functional” Impact Prediction: Computational or Knowledge-based

PM1

Hotspot

Criteria for classifying pathogenic variants

Located in a mutational hot spot and/or critical and well-established functional domain (e.g. active site of an enzyme) without benign variation.

0.5	1	2	4

If a NIPBL variant was de novo in one patient with Cornelia de Lange syndrome, with confirmed parental relationships and de novo in two additional unrelated patients with Cornelia de Lange syndrome with unconfirmed parental relationships, then …

PS2/PM6

- parental confirmed
- phenotype consistency
- number of *de novo* observations

Phenotypic consistency	Points per Proband	
	***de novo* with confirmed parental relationships**	***de novo* with unconfirmed parental relationships**
Phenotype highly specific for gene	2	1
Phenotype consistent with gene but not highly specific	1	0.5
Phenotype consistent with gene but not highly specific and high genetic heterogeneity**	0.5	0.25
Phenotype not consistent with gene	0	0

Supporting (PS2_Supporting or PM6_Supporting)	**Moderate** (PS2_Moderate or PM6)	**Strong** (PS2 or PM6_Strong)	**Very Strong** (PS2_VeryStrong or PM6_VeryStrong)
0.5	1	2	4

If a NIPBL variant was de novo in one patient with Cornelia de Lange syndrome, with confirmed parental relationships and de novo in two additional unrelated patients with Cornelia de Lange syndrome with unconfirmed parental relationships, then VeryStrong evidence level is applied (PS2_VeryStrong) based on combined point value of 4 (Table 2).

PS2/PM6 – Additional considerations

- A patient with early infantile epileptic encephalopathy and a de novo *SIK1* variant with confirmed parental relationships is awarded 1 point (as the patient's phenotype is consistent with the gene but not highly specific and the variant is de novo with confirmed parental relationships). If this patient is the only de novo occurrence for the variant, then a Moderate strength level (PS2_Moderate) is applied.

- A patient with nonsyndromic intellectual disability and a de novo *ASH1L* variant is awarded 0.5 points (as the variant is de novo with confirmed parental relationships and patient's phenotype is consistent with the gene but not highly specific and there is significant evidence of genetic heterogeneity). If this patient is the only de novo occurrence for the variant, then a Supporting strength level (PS2_Supporting) is applied.

- A patient with developmental delay but no other features of Cornelia de Lange syndrome and a de novo *NIPBL* variant with unconfirmed parental relationships is awarded zero points as this phenotype is not consistent with the gene/disease association. If this patient was the only de novo occurrence for the variant, then no de novo criteria are applied.

Questions?

Variant Interpretation Summary Example:
BRCA1 (NM_007294.3) c. 212G>C, p.(Arg71Thr)

SUMMARY

The heterozygous c.212G>C (p.R71T) variant was detected in the BRCA1 gene (NM_007294.3) and involves the last residue of exon 4 of 23.

This variant has been reported in a single affected individual with the associated disease (Harter et al., 2017; PMID: 29053726).

Functional testing has been performed for this variant and supports decreased protein function with a reduced expression of mRNA in transfected HAP1 cells. (Findlay et al, 2018, PMID 30209399).

Another amino acid substitution occurring in the same residue (p.Arg71Gly, p.Arg71Lys) has been determined to contribute to the disease associated with this gene.

The variant detected is absent in a large control population database without reported homozygotes (Karczewski et al., 2020, PMID: 32461654).

Multiple computational predictors suggest a damaging effect on gene or protein function.

Therefore, c.212G>C (p.R71T) in the BRCA1 gene is classified as ***Pathogenic.*** *Clinical correlation is recommended.*

Variant Interpretation Summary Example:

BRCA1 (NM_007294.3) c. 212G>C, p.(Arg71Thr)

Table 5 Rules for combining criteria to classify sequence variants

Pathogenic	(i) 1 Very strong (PVS1) *AND* (a) ≥1 Strong (PS1–PS4) *OR* (b) ≥2 Moderate (PM1–PM6) *OR* (c) 1 Moderate (PM1–PM6) and 1 supporting (PP1–PP5) *OR* (d) ≥2 Supporting (PP1–PP5) (ii) ≥2 Strong (PS1–PS4) *OR* (iii) 1 Strong (PS1–PS4) *AND* (a)≥3 Moderate (PM1–PM6) *OR* (b)2 Moderate (PM1–PM6) *AND* ≥2 Supporting (PP1–PP5) *OR* (c)1 Moderate (PM1–PM6) *AND* ≥4 supporting (PP1–PP5)
Likely pathogenic	(i) 1 Very strong (PVS1) *AND* 1 moderate (PM1–PM6) *OR* (ii) 1 Strong (PS1–PS4) *AND* 1–2 moderate (PM1–PM6) *OR* (iii) 1 Strong (PS1–PS4) *AND* ≥2 supporting (PP1–PP5) *OR* (iv) ≥3 Moderate (PM1–PM6) *OR* (v) 2 Moderate (PM1–PM6) *AND* ≥2 supporting (PP1–PP5) *OR* (vi) 1 Moderate (PM1–PM6) *AND* ≥4 supporting (PP1–PP5)
Benign	(i) 1 Stand-alone (BA1) *OR* (ii) ≥2 Strong (BS1–BS4)
Likely benign	(i) 1 Strong (BS1–BS4) and 1 supporting (BP1–BP7) *OR* (ii) ≥2 Supporting (BP1–BP7)
Uncertain significance	(i) Other criteria shown above are not met OR (ii) the criteria for benign and pathogenic are contradictory
