

Flux upper limits from a targeted search for extragalactic transients with the Atacama Cosmology Telescope

Carlos Hervías-Caimapo
FONDECYT postdoctoral fellow
Pontificia Universidad Católica de Chile

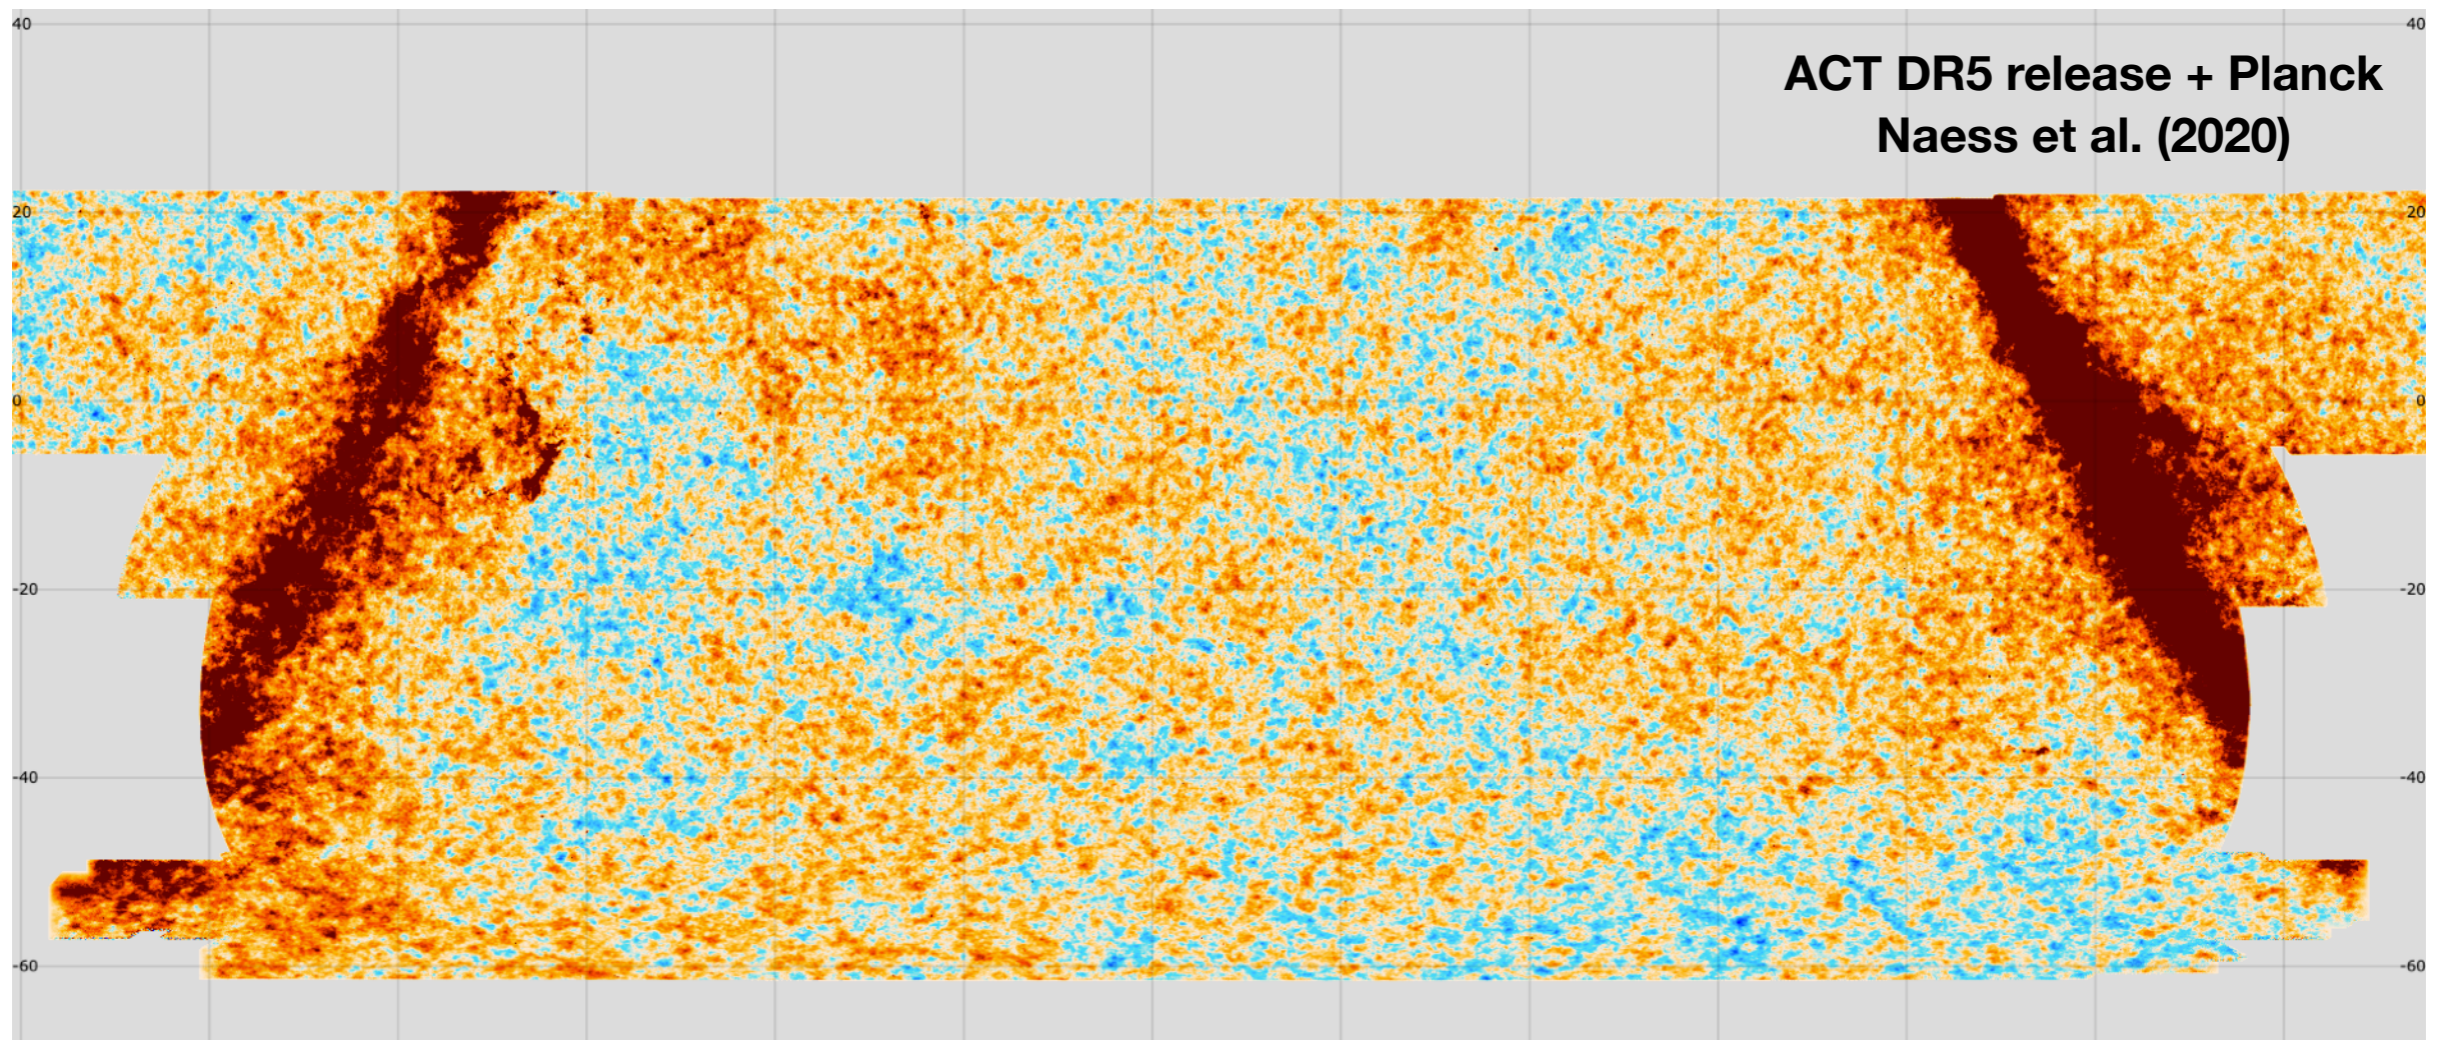

With S. Naess, K. Huffenberger, A. Hincks and the ACT collaboration

Credit: A. Hincks

Motivation

- CMB experiments scan a large fraction of the sky all day and night.
- For example, ACT observed 18k sq. deg. (40% of the sky)
- We might catch transient events in the mm. by chance.

Extragalactic transients

- Sources dominated by **synchrotron emission**: rapid ejecta from relativistic jets interaction with the circumstellar medium, accelerating free electrons.
- **Gamma Ray Bursts (GRBs)**:
 - Highly energetic explosions from very massive stars in high redshift galaxies.
 - Ejection of material at relativistic speeds.
- **Tidal Disruption Events (TDEs)**:
 - Destruction of stars close to supermassive black holes.
 - Unbound stellar debris is ejected at high speeds.
- **Supernovae (SNe)**:
 - Not expected to produce significant mm emission.
 - A few examples exist.
 - **FBOT AT 2018cow** (Ho+ 2019) inspired this work with significant mm emission and could have been observed by ACT.

AT 2018cow, Sloan Sky Digital Survey

The Atacama Cosmology Telescope

- Observed between 2008 and 2022 at multiple frequencies in the Atacama Desert, Chile.
- At an altitude of 5200 meters, with excellent conditions for millimeter astronomy.
- 6-meter primary mirror, with a resolution of 1.4 arcmin at 150 GHz (2mm).

The Atacama Cosmology Telescope

- We have many examples of extragalactic sources in catalogs.
- We can go back and look at ACT data to see if we detected something by chance, hence a **Targeted Search**.
- We use data in the period **2013-2021**, in 3 frequencies channels: **f090**, **f150** and **f220**

The Open Supernova Catalog

Welcome to the open supernova catalog! The goal of this catalog is to act as a centralized, open repository for supernova metadata, light curves, and spectra. The data on this page is scraped from various supernova data repositories, both defunct and active, and from individual papers that have published their data in machine-readable form. If you use this data, please reference the cited sources of that data. We'd also appreciate if you referenced the paper describing this catalog. Thanks!

The table below is auto-updated from a GitHub repository which encodes the data on each event as a series of ASCII files in JSON format. The entirety of the data available for any supernova can be downloaded by clicking the icon in the Data column. If you would like to contribute data yourself, please visit our contribute page. If you are aware of a source of data that is already available either online or in the literature, please add the source of data to our to do list. If you spot any mistakes, please create a new issue on our GitHub issue tracking page, or contact us via e-mail.

The Open Supernova
Catalog (Guillochon+
2014)

We limit to $z < 0.014$
Astronomical
Transients (ATs) are
also included

Observations and Results

Total number of observations, for all frequencies and arrays

SNe and ATs

- We map in limited time ranges and apply a **matched filter** to measure the flux.
- No significant detections, except one.
- ACT sensitivity for a single obs is a few tens of mJy.
- S/N of measured flux (right) from all maps consistent with random fluctuations. A few high S/N maps are consistent with noise from incomplete coverage or stripy noise.

TDEs

GRBs

Observations and Results

Table 4. Examples of the upper limits on flux density for GRBs. The columns correspond to the time range of the map in days, with 0 being the discovery time. The numbers are 95 per cent upper limits and in mJy. The position is in degrees.

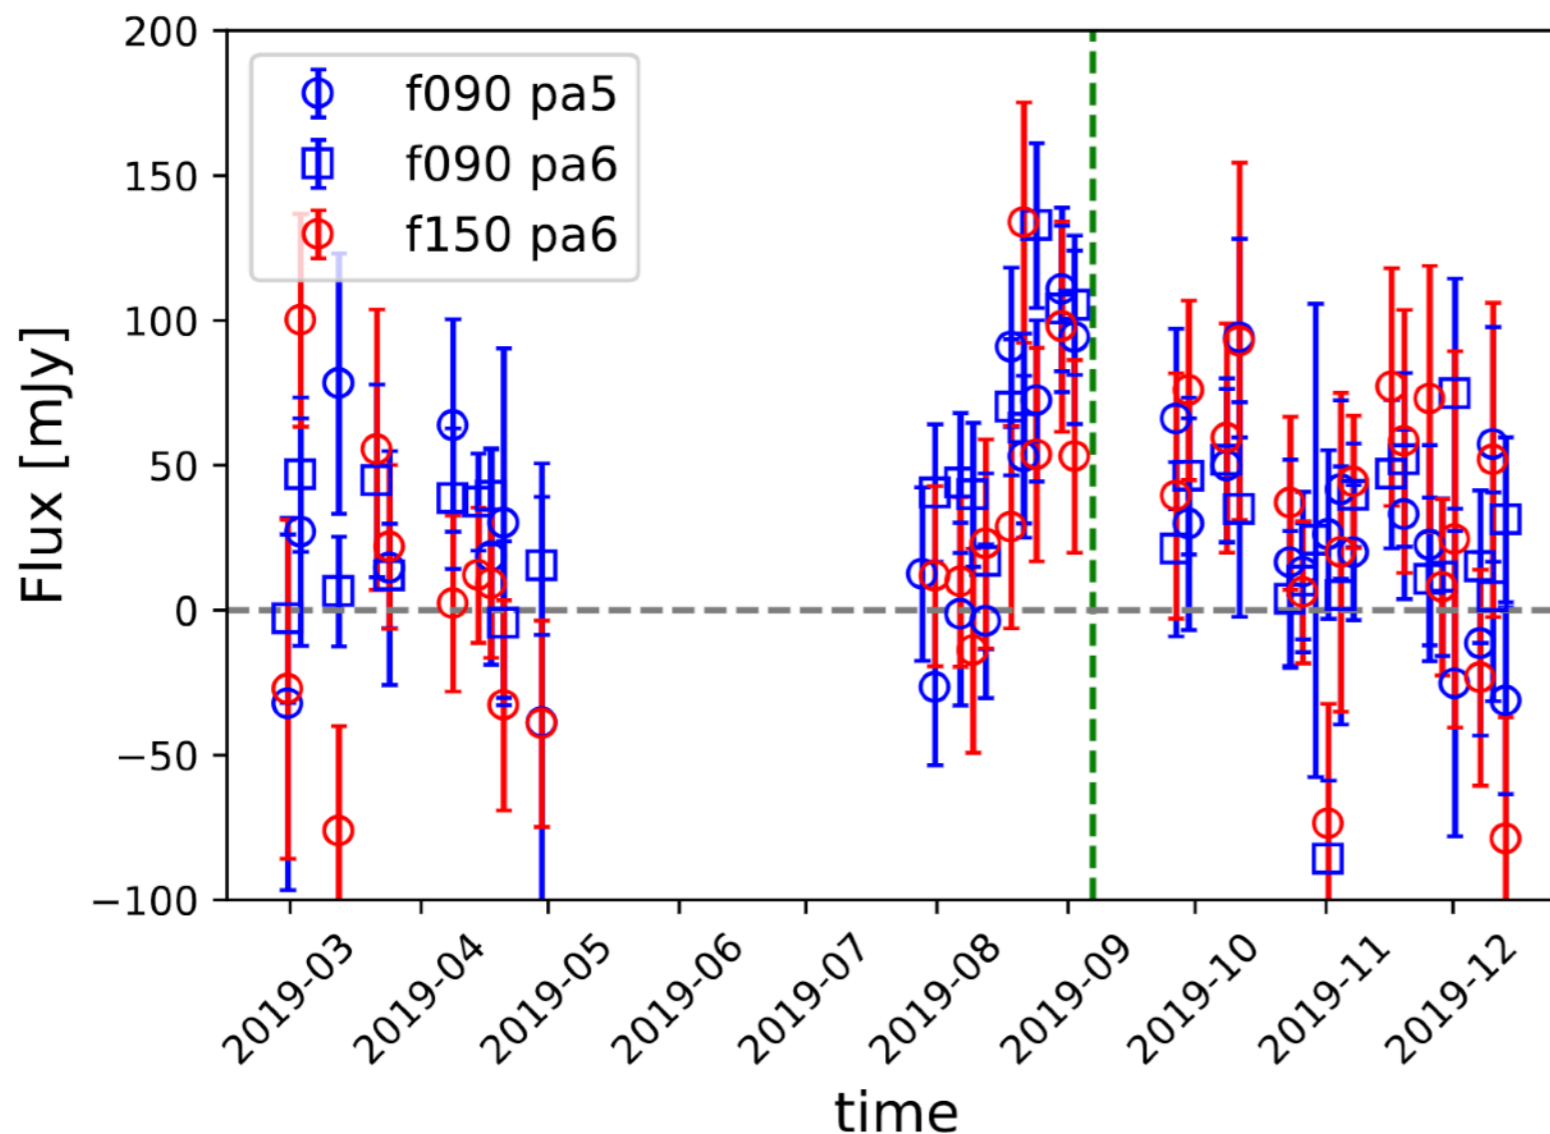

GRB Name	RA/Dec deg.	Discovery	Freq.	Time interval for the map relative to alert (in days)											
				[-3,0] mJy	[-7,0] mJy	[0,3] mJy	[3,6] mJy	[6,9] mJy	[9,12] mJy	[12,15] mJy	[0,7] mJy	[7,14] mJy	[14,21] mJy	[21,28] mJy	[0,28] mJy

This table is published in its entirety in the machine-readable format online. A portion is shown here for guidance regarding its form and content.

- We can place 95% CI flux upper limits.
- Example table for GRBs, full results can be found on [the ACT page in NASA LAMBDA](#).

AT 2019ppm

- AT 2019ppm was reported by ZTF on September 7th, 2019.
- “Known SDSS and/or MILLIQUAS QSO/AGN”
- Coincident with **NGC 2110**, a known Seyfert II galaxy.
- Detected excess over background at $\sim 5 \sigma$ in our f090 and f150 channels in the previous 28 days to discovery.
- Consistent with AGN activity of the host galaxy.

Light curve during the 2019 season, each data point is 3 days

Stacking maps

We can stack multiple events using a Maximum Likelihood approach. The flux \mathbf{f}_i of map i with covariance κ_i is modeled as

$$\mathbf{f}_i = \mathbf{a}R_i(\nu_j, t_k) + \mathbf{n}_i$$

where \mathbf{n}_i is the noise of the map, R_i is the weight of the event i normalized to a reference event, and \mathbf{a} is the detection statistic we aim to measure.

The ML solution for this is

$$\hat{a} = \frac{\sum_i R_i(\nu_j, t_k) \kappa_i \mathbf{f}_i}{\sum_i R_i(\nu_j, t_k)^2 \kappa_i} \text{ with noise inverse covariance } \mathbf{A} = \sum_i R_i(\nu_j, t_k)^2 \kappa_i$$

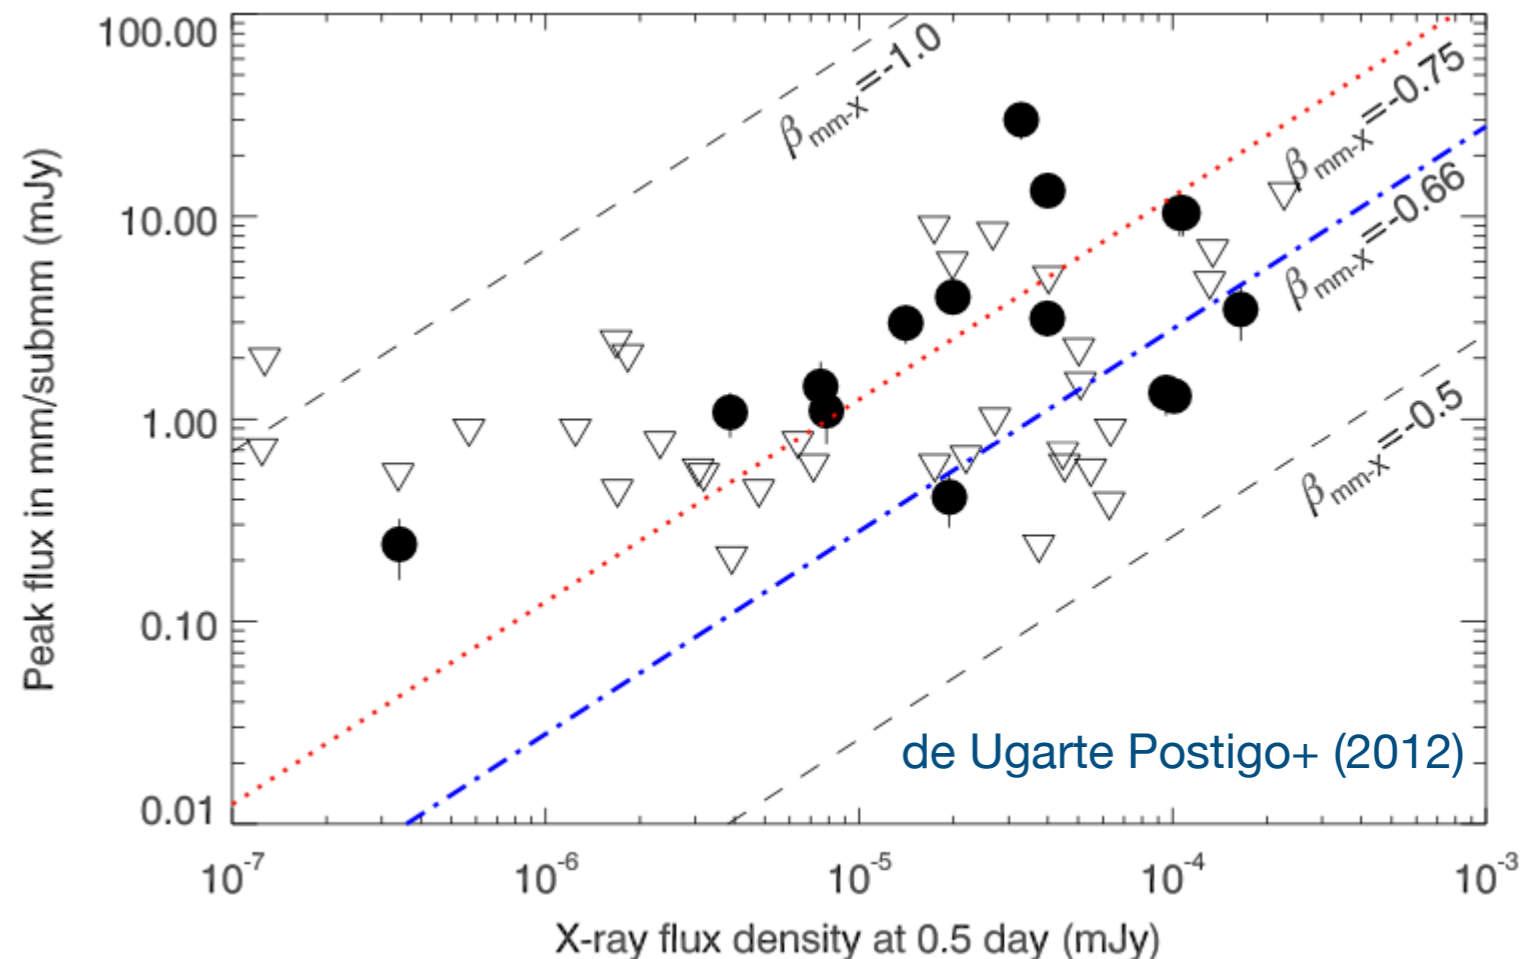

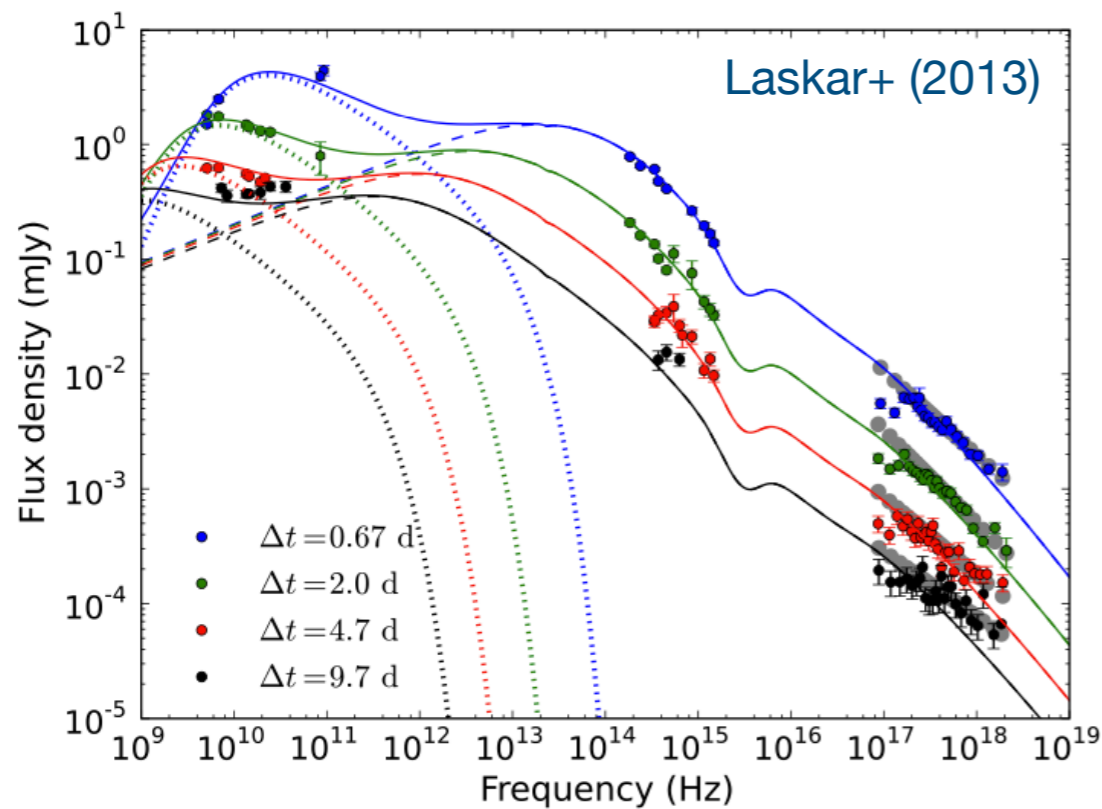

Stack the same class of transient, for a common time range and frequency, but also across time and/or frequency.

Stacking maps

The weight R_i can be chosen to be a proxy of mm flux normalized by a reference:

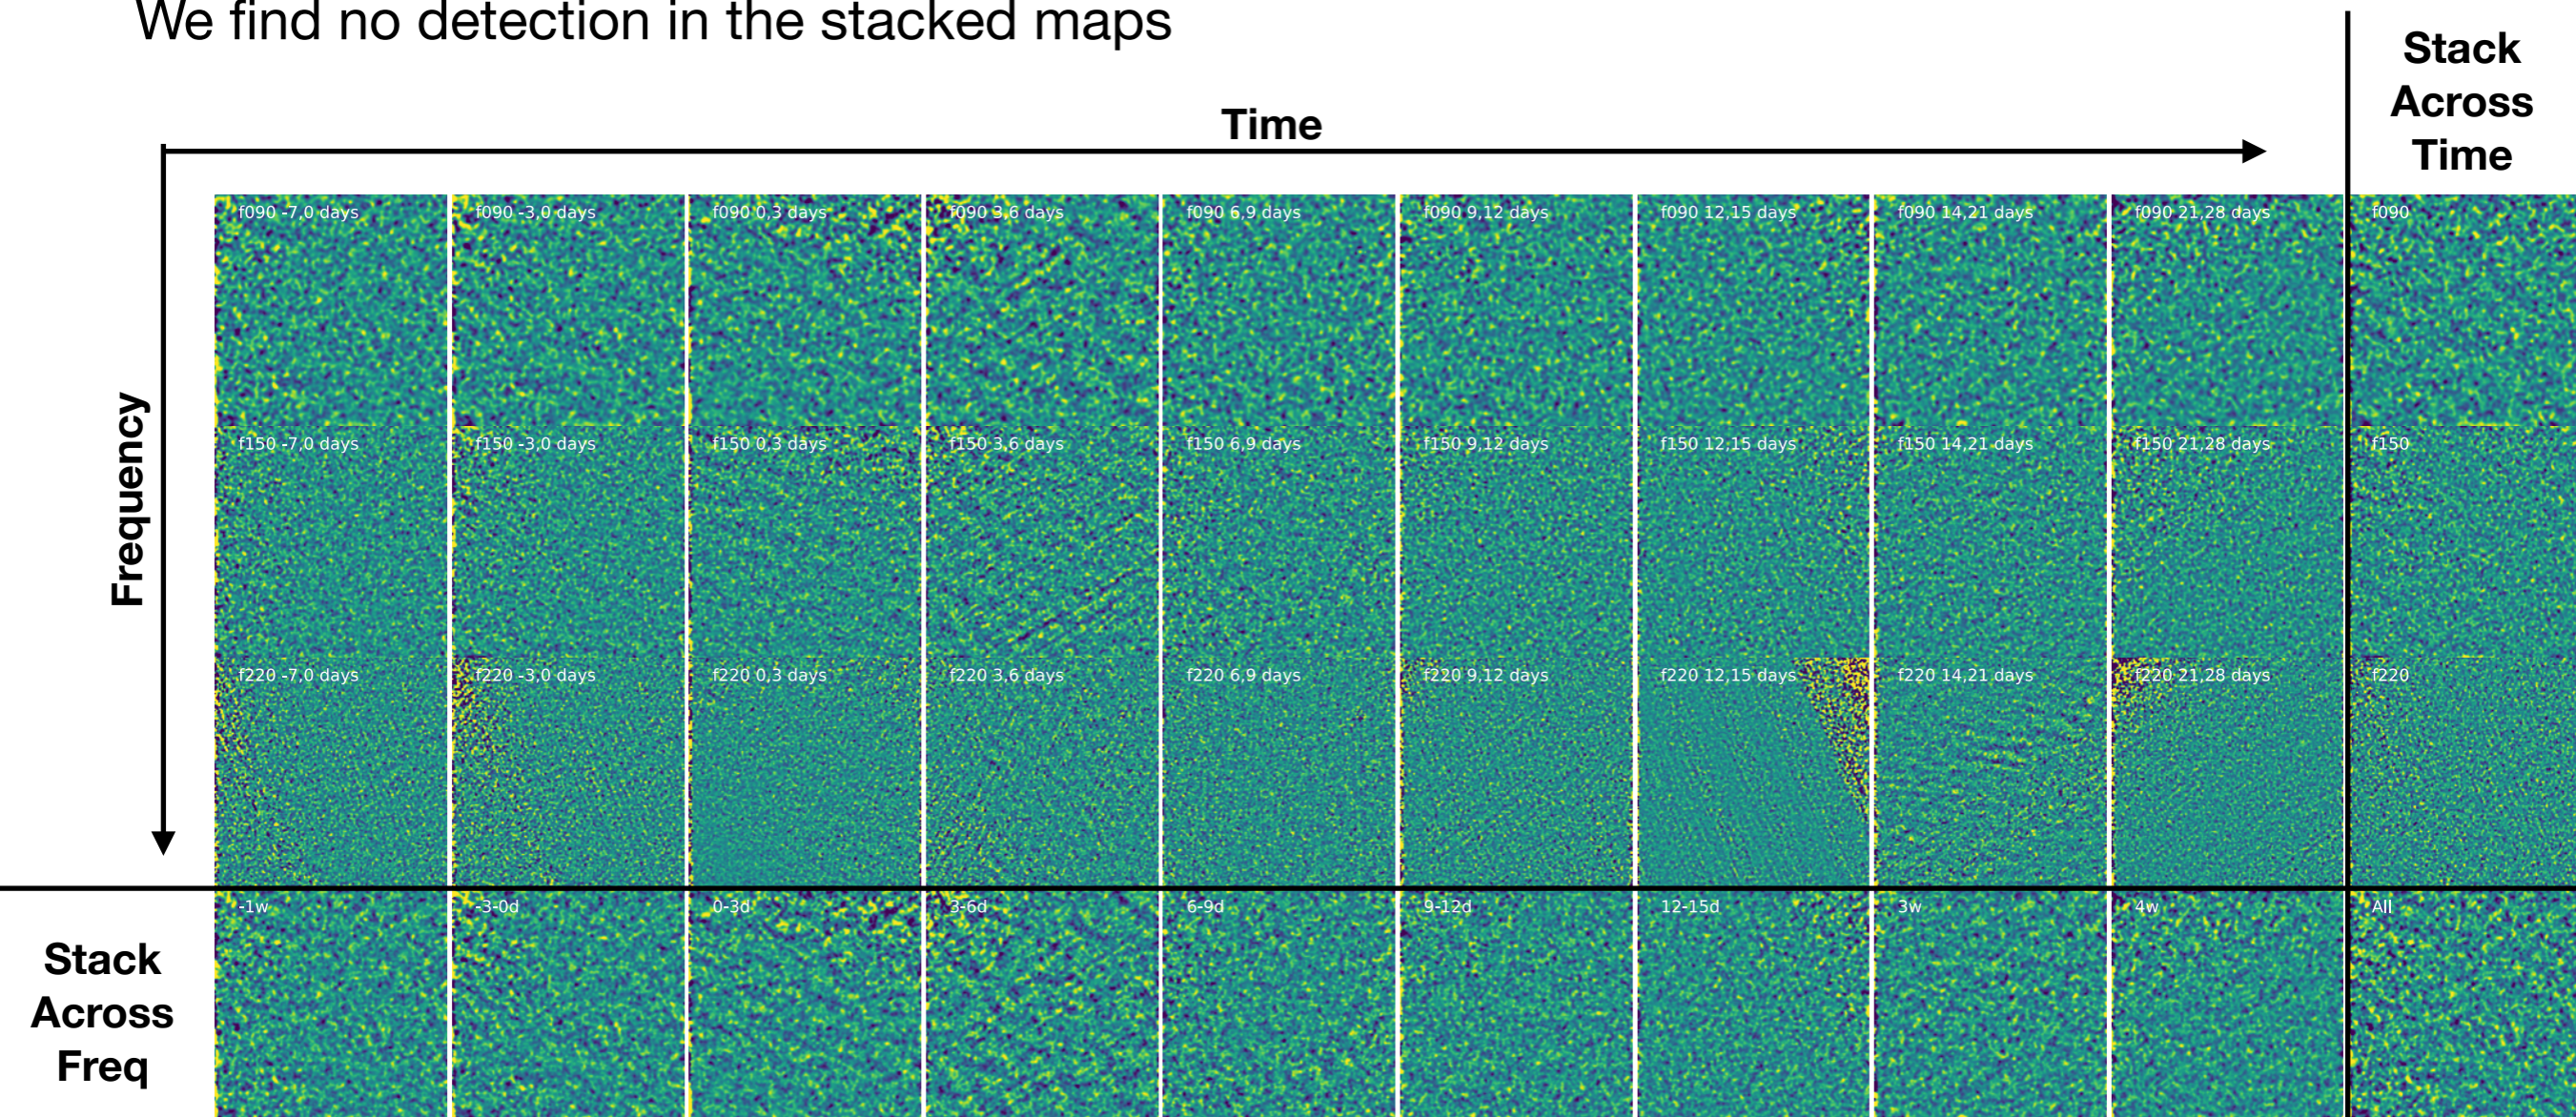

- **SNe**: we use inverse distance² with distance = 7.5 Mpc (distance to **SN 2011dh**)
- **TDEs**: Same as SNe, with distance = 92.6 Mpc (distance to **TDE ASASSN-14li**)
- **GRBs**: we use the 24-hour X-ray flux, normalized to the flux of **GRB 130427A**, our reference. We transform across frequency and time using the model from Laskar+ (2013) and van der Horst (2014).

We stack **GRBs**, **TDEs**, only **core-collapse SNe** and only **type Ia SNe**.

Stacking maps

We find no detection in the stacked maps

Stacked results for GRBs

Stacking maps

We find no detection in the stacked maps

Table 8. Characteristic luminosity for stacked GRBs. The units are $10^9 L_{\odot}$. This is calculated from the mean mm flux for the reference GRB 130427A as explained in Section 4.2.4. We stress that when weighting the stacks and averaging across time and frequency, we make the explicit assumption that every GRB in the stack is a copy of GRB 130427A, scaled by a factor. Under this assumption, the stacked map would have the mean mm flux of GRB 130427A, which is located at a distance of 1852 Mpc. We also show the characteristic luminosity for the reference in each stacked map, where the flux is scaled from the model SED.

Measured flux from stacks transformed to characteristic luminosity, assuming the distance to the reference GRB 130427A.

Even stacking all GRBs across all frequencies and time intervals, we reach S/N~1/3

What about future surveys?

- **Simons Observatory (SO)** is about to start operations.
- Much better sensitivity:
 - 4.7x the amount of detectors in f090, f150, f220.
 - ~3x more coverage due to regular cadence and improvements in observing efficiency.
 - All this would **improve the GRB stack from S/N 1/3 -> 1.3**
 - On top of that, 3 other freq. channels + **Advanced SO** (recently approved) would double the amount of detectors and time.
- Searching transients in ACT data will inform our operation to find transients in SO.
- At the end of decade **CMB-S4** will improve even more + transient alerts on almost real time
- Both SO and CMB-S4 are predicted to detect dozens of GRBs + other sources. See Eftekhari+ 2021 and talk by E. Biermann.

SO: Analysis Working Group ST, Sources and Transients

- ACT work and experience on transients can be applied to SO: Large Aperture Telescope (LAT) instrument is very similar to ACT, and also the same people.
- SO will have a scanning strategy with regular cadence.
- **Map-based search:**
 - Based on **Depth-1 maps**, which map a single pass of the telescope.
 - Simulations of observations, injection of fake transients.
 - Forecast how well we can find them and measure their flux.
- **Time stream-based search:**
 - Fast signals could be detected directly in the time stream, such as Pulsars and FRBs.
 - Forecast a potential detections.

Credit: S. Naess

Summary

- CMB experiments scan the sky constantly -> serendipitous detection of mm transients.
- ACT is looking in the time domain: Blind search for transients (see talk by Y. Li).
- This talk was about a targeted search for GRBs, TDEs, SNEs and assorted ATs from catalogs.
- We find no transients, except one event consistent with AGN activity from the host galaxy.
- Stacking multiple events together can improve S/N.
- Much better sensitivity from future surveys, techniques in this work can be used.
- We should detect mm transient regularly with SO and CMB-S4. Stay tuned.

Thank you!
